

Replication materials

Household trajectories of resilience to acute malnutrition in the Kenyan drylands

Ravi Bhavnani, Nina Schlager, Mirko Reul and Karsten Donnay

This file contains replication information for the analysis performed in Bhavnani et al. (2023). *'Household trajectories of resilience to acute malnutrition in the Kenyan drylands'*, *Frontiers in Sustainable Food Systems*, DOI: 10.3389/fsufs.2023.1091346

There are 3 distinct steps in the analysis:

1. Data preparation and resilience calculation
 - Geo-coding of wards
 - Ward resilience to acute malnutrition
 - External stressor intensity
2. Latent Class Mixed Model (LCMM)
3. Cox Regression Analysis

Please also see `readme.txt` for additional information on the data inputs and variable coding. Note that most illustrations featured in the published paper have been re-processed in *Inkscape* to maximize clarity.

1. Data preparation and resilience calculation

1.1 Geo-coding of wards

The raw NDMA data used is `MUAC_all.csv`. All observations are geocoded at the ward level (`adm3`). We therefore compare ward names provided by the NDMA with spatial information from the GADM project. `geocoding_wardnames_all.txt` lists all differences. The adjusted spatial information is stored in `KEN_adm3-ndma.shp` and can be found in the sub-directory `gadm36_KEN_shp`. `helper_functions_geocoding.R` includes a function to check the number of incorrectly coded observations in a sample.

```
# load helper function
source("code/helper_functions_geocoding.R")

# load MUAC data
df <- read.csv("data/MUAC_all.csv")

# re-code county (adm1) names
df$adm1 <- dplyr::recode(df$adm1,
                        "Tana river" = "Tana River",
                        "West pokot" = "West Pokot",
                        "Tharaka Nithi" = "Tharaka-Nithi")

# re-assign county (adm1) names
df <- df %>% mutate(
```

```

adm1 = replace(adm1, adm3 == "Kamarandi", "Embu"),
adm1 = replace(adm1, adm3 == "Nanighi", "Garissa"),
adm1 = replace(adm1, adm3 == "Kapenguria", "West Pokot"),
adm1 = replace(adm1, adm3 == "Riwo", "Baringo")
)

1.2 Ward resilience to acute malnutrition

We calculate ward resilience (r_{adm3}) on the basis of monthly MUAC information of individual children in 22 counties between 2016 and 2020.

```
# define MUAC threshold in mm (Risk of acute malnutrition, WHO)
THRESHOLD = 135

# calculate ward resilience
resilience_adm3 <- df
resilience_adm3 <- resilience_adm3 %>%
  group_by(adm3, date) %>%
  dplyr::mutate(id_r = cur_group_id())
excluded_hh = 0
dfs <- list()
for(i in 1:length(unique(resilience_adm3$id_r))) {

  # subset by adm3
  dat <- subset(resilience_adm3,
                resilience_adm3$id_r==
                unique(resilience_adm3$id_r)[i])

  # calculate MUAC distance to threshold
  # - difference calculation is entry-wise
  above <- subset(dat, dat$MUAC > THRESHOLD)
  below <- subset(dat, dat$MUAC <= THRESHOLD)
  above$diff = above$MUAC - THRESHOLD
  below$diff = THRESHOLD - below$MUAC
  # construct joint data frame
  if(nrow(below) > 0 && nrow(above) > 0) {
    dat <- rbind(above, below)
  } else {
    if(nrow(above) > 0)
      dat <- above
    if(nrow(below) > 0)
      dat <- below
  }

  # - integrate/sum over the differences above & below threshold
  # - relative weight not up/down-ward biased due to value range!
  if (nrow(above)>0){

1.3 External stressor intensity

We include information on climate, conflict and food price stressor intensity at the county-month-level to identify typical ward-resilience trajectories.

- `kenya_climate_monthadm1.RData`: The climate data are based on the “MOD13A3 v006” NDVI data available here. For each county-month in our sample, we calculate spatially averaged NDVI.
- `kenya_markets_monthadm1.RData`: Information regarding market price developments for 1kg maize are provided by the NDMA via expert interviews. We calculate monthly deviation rates from a three-year average and categorize each month as stressed or not, where stressor intensity is defined as the mean price increase above the long-term average.
- `kenya_conflict_monthadm1.RData`: Lastly, to account for the intensity of conflict, we draw on the Uppsala Conflict Data Program’s Georeferenced Events Dataset (see Sundberg & Melander, 2013).

Figure 2: Average resilience for the period between 2016 and 2020 with smaller values indicating lower resilience. Blue dots display the mean proportion of malnourished children relative to the population size per ward for the same period(Figure 2, right)

2. Latent class mixed model (LCMM)

We fit a Latent Class Mixed Model (LCMM) to identify latent patterns in the observed ward resilience and use the fitted model to classify wards into groups with similar resilience trajectories.

We include below the code we used to identify the best model based on the smallest BIC, depending on alternative link functions and 1-10 classes. Note that as a function of the slightly different, anonymised input data, it's impossible to directly replicate the merger for the ward-level resilience trajectories and figures as reported in the article. To save computing time, we provide this information, i.e. the resilience trajectory class of each household (excluding ward-names) in a separate file called `household_all.csv`.

Figure 5: Observed trajectories of ward resilience to acute malnutrition at monthly intervals (Figure 3, top)

Figure 6: Resilience trajectories per assigned latent class for Kenyan wards (Figure 4)

3. Cox regression

Second, we use cox regression analysis to explore household risk depending on ward-resilience trajectory, while controlling for a minimal set of control variables.

The raw data used is `household_all.csv`.

To perform the cox regression analysis, we provide the following variables

- *AMN_dummy*: binary variable indicating that a household is malnourished, i.e. if min 1 observation is MUAC < 125mm
- *class*: assigned ward-resilience trajectory (increase, decrease, chronic, robust)
- *time*: number of survey months
- *switch_below*: binary variable indicating that a household becomes malnourished at time t
- *switch_recover*: binary variable indicating that a household recovers from malnutrition at time t
- *status*: categorical variable indicating household switches from normal nutrition to undernourished and vice versa
- *tevent*: time in months until switch in status

Note that the above calculations are rather data-intensive and were processed separately. In addition, we include the following fixed household characteristics as background variables:

- *gender household head* (female, male)
- *education household head* (true, false)
- *livelihood* (pastoralist, other)
- *water source* (safe, unsafe)

`rules_coding_agg.txt` provides a summary of the coding and aggregation rules.

```
# load household data
df <- read.csv("data/household_all.csv", stringsAsFactors = TRUE)

# use chronic as a reference category
df$class = relevel(df$class, ref = "chronic")

# recode status
df$status2 <- as.integer(df$status)
